Using the CLI

Table of Contents

| Browsing resources | 1 |
|------------------------------------|---|
| Deleting resources | 1 |
| Installing Runtimes and Connectors | |
| Running the Operator | |
| Subscribing to events | 2 |

You can get help on the available commands via:

```
funktion
```

Browsing resources

To list all the resources of different kind via:

```
funktion get connector
funktion get subscription
funktion get function
funktion get runtime
```

or to save typing you can use:

```
funktion get c
funktion get s
funktion get f
funktion get r
```

Deleting resources

You can delete a Connector or Subscription via:

```
funktion delete connector foo
funktion delete subscription bar
funktion delete function whatnot
funktion delete runtime nodejs
```

Or to remove all the Subscriptions or Connectors use --all

```
funktion delete subscription --all
```

Installing Runtimes and Connectors

To install the default function runtimes and connectors into your namespace type the following:

```
funktion install --all-connectors
```

There's over 200 connectors provided out of the box. If you only want to install a number of them you can specify their names as parameters

funktion install ampp kafka timer

To just get a feel for what connectors are available without installing them try:

```
funktion install --list-connectors
```

or for short:

```
funktion install -l
```

Running the Operator

You can run the funktion operator from the command line if you prefer:

```
funktion operate
```

Though ideally we'd run the funktion application inside kubernetes; via a helm chart, kubectl apply or the Run… button in the fabric8 developer console

Subscribing to events

To create a new subscription for a connector try the following:

```
funktion subscribe --from timer://bar?period=5000 --to http://foo/
```

This will generate a new Subscription which will result in a new Deployment being created and one or more Pods should spin up.

Note that you must be running the Operator as described in the section above; its the Operator which actually creates a Deployment for each Subscription.

Also note that the first time you try out a new Connector kind it may take a few moments to download the docker image for this connector - particularly the first time you use a connector.

Once a pod has started for the Deployment you can then view the logs of a subscription via kubectl

```
kubectl logs -f nameOfSubscription[TAB]
```

Scaling a Subscription

If you want to stop a subscription type:

kubectl scale --replicas=0 deployment nameOfSubscription

To start it again:

kubectl scale --replicas=1 deployment nameOfSubscription

Using kubectl directly

You can also create a Subscription using kubectl if you prefer:

kubectl apply -f https://github.com/fabric8io/funktionoperator/blob/master/examples/subscription1.yml

You can view all the Connectors and Subscriptions via:

kubectl get cm

Or delete them via

kubectl delete cm nameOfConnectorOrSubscription
